The main aim of Professor Tania Lincoln's research is to find out how and why psychotic symptoms arise and how they are maintained. This research involves identifying factors on an individual level and in the environment that may make a person vulnerable to developing psychosis. In her recent work she has laid a strong emphasis in looking at the dynamic interplay between people's vulnerability on the one hand and their emotional and cognitive information processing on the other. She uses this knowledge to improve psychological interventions for people with psychotic disorders. Presently, she is investigating the efficacy of different interventions tailored to hallucinations, delusions, negative symptoms and psychosis and trauma. She is also committed to improving prevention for psychosis and other mental health problems using both specific and transdiagnostic approaches.
